\$#+K!Introduction

Object Graphics Library (OGL) is a C++ library supporting the creation and manipulation of simple and complex graphic images on a canvas.

It can be found in the directory `utils/ogl/src` in the wxWindows distribution. The file `ogl.h` must be included to make use of the library.

Please see [OGL overview](#) for a general description how the object library works. For details, please see the [class reference](#).

\$#+K!OGLEdit: a sample OGL application

OGLEdit is a sample OGL application that allows the user to draw, edit, save and load a few shapes. It should clarify aspects of OGL usage, and can act as a template for similar applications. OGLEdit can be found in `samples/ogledit` in the OGL distribution.

{bmc ogledit.bmp}

The wxWindows document/view model has been used in OGL, to reduce the amount of housekeeping logic required to get it up and running. OGLEdit also provides a demonstration of the Undo/Redo capability supported by the document/view classes, and how a typical application might implement this feature.

\$#+K!Change log

Version 3.0, September 8th 1998

{bmc bullet.bmp} Version for wxWindows 2.0.

{bmc bullet.bmp} Various enhancements especially to wxDrawnShape (multiple metafiles, for different orientations).

{bmc bullet.bmp} More ability to override functions e.g. OnSizeDragLeft, so events can be intercepted for Do/Undo.

Version 2.0, June 1st 1996

{bmc bullet.bmp} First publicly released version.

\$#+K! **OGLEdit files**

OGLEdit comprises the following source files.

{bmc bullet.bmp} doc.h, doc.cpp: MyDiagram, DiagramDocument, DiagramCommand, MyEvtHandler classes related to diagram functionality and documents.

{bmc bullet.bmp} view.h, view.cpp: MyCanvas, DiagramView classes related to visualisation of the diagram.

{bmc bullet.bmp} ogledit.h, ogledit.cpp: MyFrame, MyApp classes related to the overall application.

{bmc bullet.bmp} palette.h, palette.cpp: EditorToolPalette implementing the shape palette.

t opic2
b rowse00005
K OGLEdit files
E nableButton("Up");ChangeButtonBinding("Up", "JumpId(`ogl.hlp', `ogledit')")

\$#+K! How OGLEdit works

OGLEdit defines a DiagramDocument class, each of instance of which holds a MyDiagram member which itself contains the shapes.

In order to implement specific mouse behaviour for shapes, a class MyEvtHandler is defined which is 'plugged into' each shape when it is created, instead of overriding each shape class individually. This event handler class also holds a label string.

The DiagramCommand class is the key to implementing Undo/Redo. Each instance of DiagramCommand stores enough information about an operation (create, delete, change colour etc.) to allow it to carry out (or undo) its command. In DiagramView::OnMenuCommand, when the user initiates the command, a new DiagramCommand instance is created which is then sent to the document's command processor (see wxWindows manual for more information about doc/view and command processing).

Apart from menu commands, another way commands are initiated is by the user left-clicking on the canvas or right-dragging on a node. MyCanvas::OnLeftClick in view.cpp shows how the appropriate wxClassInfo is passed to a DiagramCommand, to allow DiagramCommand::Do to create a new shape given the wxClassInfo.

The MyEvtHandler right-drag methods in doc.cpp implement drawing a line between two shapes, detecting where the right mouse button was released and looking for a second shape. Again, a new DiagramCommand instance is created and passed to the command processor to carry out the command.

DiagramCommand::Do and DiagramCommand::Undo embody much of the interesting interaction with the OGL library. A complication of note when implementing undo is the problem of deleting a node shape which has one or more arcs attached to it. If you delete the node, the arc(s) should be deleted too. But multiple arc deletion represents more information that can be incorporated in the existing DiagramCommand scheme. OGLEdit copes with this by treating each arc deletion as a separate command, and sending Cut commands recursively, providing an undo path. Undoing such a Cut will only undo one command at a time - not a one to one correspondence with the original command - but it's a reasonable compromise and preserves Do/Undo while keeping our DiagramCommand class simple.

b
rowse00006
K
How OGLEdit works
E
nableButton("Up");ChangeButtonBinding("Up", "JumpId(`ogl.hlp', `ogledit')")

\$#+K! Possible enhancements

OGLEdit is very simplistic and does not employ the more advanced features of OGL, such as:

- {bmc bullet.bmp} attachment points (arcs are drawn to particular points on a shape)
- {bmc bullet.bmp} metafile and bitmaps shapes
- {bmc bullet.bmp} divided rectangles
- {bmc bullet.bmp} composite shapes, and constraints
- {bmc bullet.bmp} creating labels in shape regions
- {bmc bullet.bmp} arc labels (OGL has support for three movable labels per arc)
- {bmc bullet.bmp} spline and multiple-segment line arcs
- {bmc bullet.bmp} adding annotations to node and arc shapes
- {bmc bullet.bmp} line-straightening (supported by OGL) and alignment (not supported directly by OGL)

These could be added to OGLEdit, at the risk of making it a less useful example for beginners.

\$#+K! **wxShapeEvtHandler**

wxShapeEvtHandler is a class from which wxShape (and therefore all shape classes) are derived. A wxShape also contains a pointer to its current wxShapeEvtHandler. Event handlers can be swapped in and out, altering the behaviour of a shape. This allows, for example, a range of behaviours to be redefined in one class, rather than requiring each shape class to be subclassed.

\$#+K! OGL overview

wxShapeCanvas, derived from **wxCanvas**, is the drawing area for a number of wxShape instances. Everything drawn on a wxShapeCanvas is derived from wxShape, which provides virtual member functions for redrawing, creating and destroying resize/selection 'handles', movement and erasing behaviour, mouse click behaviour, calculating the bounding box of the shape, linking nodes with arcs, and so on.

The way a client application copes with 'damage' to the canvas is to erase (white out) anything should no longer be displayed, redraw the shape, and then redraw everything on the canvas to repair any damage. If quick edit mode is on for the canvas, the complete should be omitted by OGL and the application.

Selection handles (called control points in the code) are implemented as wxRectangleShapes.

Events are passed to shapes by the canvas in a high-level form, for example **OnLeftClick**, **OnBeginDragLeft**, **OnDragLeft**, **OnEndDragLeft**. The canvas decides what is a click and what is a drag, whether it is on a shape or the canvas itself, and (by interrogating the shape) which attachment point the click is associated with.

In order to provide event-handling flexibility, each shapes has an 'event handler' associated with it, which by default is the shape itself (all shapes derive from wxShapeEvtHandler). An application can modify the event-handling behaviour simply by plugging a new event handler into the shape. This can avoid the need for multiple inheritance when new properties and behaviour are required for a number of different shape classes: instead of overriding each class, one new event handler class can be defined and used for all existing shape classes.

A range of shapes have been predefined in the library, including rectangles, ellipses, polygons. A client application can derive from these shapes and/or derive entirely new shapes from wxShape.

Instances of a class called wxDiagram organise collections of shapes, providing default file input and output behaviour.

\$#+KI wxDividedShape overview

Classes: [wxDividedShape](#)

A wxDividedShape is a rectangle with a number of vertical divisions. Each division may have its text formatted with independent characteristics, and the size of each division relative to the whole image may be specified.

Once a wxDividedShape has been created, the user may move the divisions with the mouse. By pressing Ctrl while right-clicking, the region attributes can be edited.

Here are examples of creating wxDividedShape objects:

```
/*
 * Divided rectangle with 3 regions
 *
 */

wxDividedShape *dividedRect = new wxDividedShape(50, 60);

wxShapeRegion *region = new wxShapeRegion;
region->SetProportions(0.0, 0.25);
dividedRect->AddRegion(region);

region = new wxShapeRegion;
region->SetProportions(0.0, 0.5);
dividedRect->AddRegion(region);

region = new wxShapeRegion;
region->SetProportions(0.0, 0.25);
dividedRect->AddRegion(region);

dividedRect->SetSize(50, 60); // Allow it to calculate region
sizes
dividedRect->SetPen(wxBLACK_PEN);
dividedRect->SetBrush(wxWHITE_BRUSH);
dividedRect->Show(TRUE);
dividedRect->NameRegions();

/*
 * Divided rectangle with 3 regions, rounded
 *
 */

wxDividedShape *dividedRect3 = new wxDividedShape(50, 60);
dividedRect3->SetCornerRadius(-0.4);

region = new wxShapeRegion;
region->SetProportions(0.0, 0.25);
dividedRect3->AddRegion(region);

region = new wxShapeRegion;
```

dividedRect3->Show(TRUE);
dividedRect3->NameRegions();
```

\$#+K!wxCompositeShape overview

Classes: [wxCompositeShape](#), [wxOGLConstraint](#)

The wxCompositeShape allows fairly complex shapes to be created, and maintains a set of constraints which specify the layout and proportions of child shapes.

Add child shapes to a wxCompositeShape using [AddChild](#), and add constraints using [AddConstraint](#).

After children and shapes have been added, call [Recompute](#) which will return TRUE if the constraints could be satisfied, FALSE otherwise. If constraints have been correctly and consistently specified, this call will succeed.

If there is more than one child, constraints must be specified: OGL cannot calculate the size and position of children otherwise. Don't assume that children will simply move relative to the parent without the use of constraints.

To specify a constraint, you need three things:

1. a constraint type, such as `gyCONSTRAINT_CENTRED_VERTICALLY`;
2. a reference shape, with respect to which other shapes are going to be positioned - the *constraining* shape;
3. a list of one or more shapes to be constrained: the *constrained* shapes.

The constraining shape can be either the parent of the constrained shapes, or a sibling. The constrained shapes must all be siblings of each other.

For an exhaustive list and description of the available constraint types, see the [wxOGLConstraint constructor](#). Note that most constraints operate in one dimension only (vertically or horizontally), so you will usually need to specify constraints in pairs.

You can set the spacing between constraining and constrained shapes by calling [wxOGLConstraint::SetSpacing](#).

Finally, a wxCompositeShape can have *divisions*, which are special child shapes of class wxDivisionShape (not to be confused with wxDividedShape). The purpose of this is to allow the composite to be divided into user-adjustable regions (divisions) into which other shapes can be dropped dynamically, given suitable application code. Divisions allow the child shapes to have an identity of their own - they can be manipulated independently of their container - but to behave as if they are contained with the division, moving with the parent shape. Divisions boundaries can themselves be moved using the mouse.

\$#+K! **wxLineShape::AddArrow**

```
void AddArrow(WXTYPE type, bool end = ARROW_POSITION_END, double  
arrowSize = 10.0, double xOffset = 0.0, const wxString& name = "",  
wxPseudoMetaFile *mf = NULL, long arrowId = -1)K
```

Adds an arrow (or annotation) to the line.

type may currently be one of:

ARROW_HOLLOW_CIRCLE Hollow circle.

ARROW_FILLED_CIRCLE Filled circle.

ARROW_ARROW Conventional arrowhead.

ARROW_SINGLE_OBLIQUE Single oblique stroke.

ARROW_DOUBLE_OBLIQUE Double oblique stroke.

ARROW_DOUBLE_METAFILE Custom arrowhead.

end may currently be one of:

ARROW_POSITION_END Arrow appears at the end.

ARROW_POSITION_START Arrow appears at the start.

arrowSize specifies the length of the arrow.

xOffset specifies the offset from the end of the line.

name specifies a name for the arrow.

mf can be a wxPseduoMetaFile, perhaps loaded from a simple Windows metafile.

arrowId is the id for the arrow.

^K `AddArrow`

\$#+K! **wxLineShape::AddArrowOrdered**

void AddArrowOrdered(wxArrowHead *arrow, wxList& referenceList, int end)^K

Add an arrowhead in the position indicated by the reference list of arrowheads, which contains all legal arrowheads for this line, in the correct order. E.g.

Reference list: a b c d e
Current line list: a d

Add c, then line list is: a c d.

If no legal arrowhead position, return FALSE. Assume reference list is for one end only, since it potentially defines the ordering for any one of the 3 positions. So we don't check the reference list for arrowhead position.

\$#+K!wxShape::CalcSimpleAttachment

wxRealPoint CalcSimpleAttachment(const wxRealPoint& *pt1*, const wxRealPoint& *pt2*, int *nth*, int *noArcs*, wxLineShape* *line*)^K

Assuming the attachment lies along a vertical or horizontal line, calculates the position on that point.

Parameters

pt1

The first point of the line representing the edge of the shape.

pt2

The second point of the line representing the edge of the shape.

nth

The position on the edge (for example there may be 6 lines at this attachment point, and this may be the 2nd line).

noArcs

The number of lines at this edge.

line

The line shape.

Remarks

This function expects the line to be either vertical or horizontal, and determines which.

^wxShape::CalcSimpleAttachment

\$#+K! **wxShape::Copy**

void Copy(wxShape& copy)^K

Copy this shape into *copy*. Every derived class must have one of these, and each Copy implementation must call the derived class's implementation to ensure everything is copied. See also [wxShape::CreateNewCopy](#).

^W **wxShape::Copy**

^W **xshapecopy**

^B **rowse00222**

^K **wxShape Copy**

^E **nableButton("Up");ChangeButtonBinding("Up", "JumpId(`ogl.hlp', `wxshape')")**

^K **Copy**

\$#+K! **wxShape::CreateNewCopy**

wxShape* **CreateNewCopy(bool resetMapping = TRUE, bool recompute = TRUE)**^K

Creates and returns a new copy of this shape (calling wxShape::Copy). Do not override this function.

This function should always be used to create a new copy, since it must do special processing for copying constraints associated with constraints.

If *resetMapping* is TRUE, a mapping table used for complex shapes is reset; this may not be desirable if the shape being copied is a child of a composite (and so the mapping table is in use).

If *recompute* is TRUE, wxShape::Recompute is called for the new shape.

Remarks

This function uses the wxWindows dynamic object creation system to create a new shape of the same type as 'this', before calling Copy.

If the event handler for this shape is not the same as the shape itself, the event handler is also copied using wxShapeEvtHandler::CreateNewCopy.

void OnLeftClick(double x, double y, int keys =0, int attachment = 0)^K

Called when the shape receives a left mouse click event.

^W **wxShapeEvtHandler::OnLeftClick**

^T **topic281**

^B **rowse00375**

^K **wxShapeEvtHandler OnLeftClick**

^E **nableButton("Up");ChangeButtonBinding("Up", "JumpId(`ogl.hlp', `wxshapeevthandler')")**

^K **OnLeftClick**

\$#+K! **wxShapeEvtHandler::OnMoveLink**

void OnMoveLink(wxDC& dc, bool moveControlPoints=TRUE)^K

Called when the line attached to an shape need to be repositioned, because the shape has moved.

^wxShapeEvtHandler::OnMoveLink

^topic282

^browse00376

^K wxShapeEvtHandler OnMoveLink

^EnableButton("Up");ChangeButtonBinding("Up", "JumpId(`ogl.hlp', `wxshapeevthandler')")

^K OnMoveLink

\$#+K! **wxShapeEvtHandler::OnMoveLinks**

void OnMoveLinks(wxDC& dc)^K

Called when the lines attached to an shape need to be repositioned, because the shape has moved.
